Week 5: Condorcet Dimensions Problem: Exploration 1

Questions

- When you do research in your field, approximately how many theorems / results do you use in a paper and how well do you have to understand them, in general?
- The literature in Condorcet dimensions uses a general $\alpha \in (0, 1]$ to represent the strict upper bound ratio of voters who prefer a candidate outside the Condorcet Winning Set. Is there an advantage of this generalization in modeling the problem for the usual $\alpha = 1/2$ using this generalization? Is there an example of where something like this was useful in your research / other research papers you've read?
